Buildings account for about 40 percent

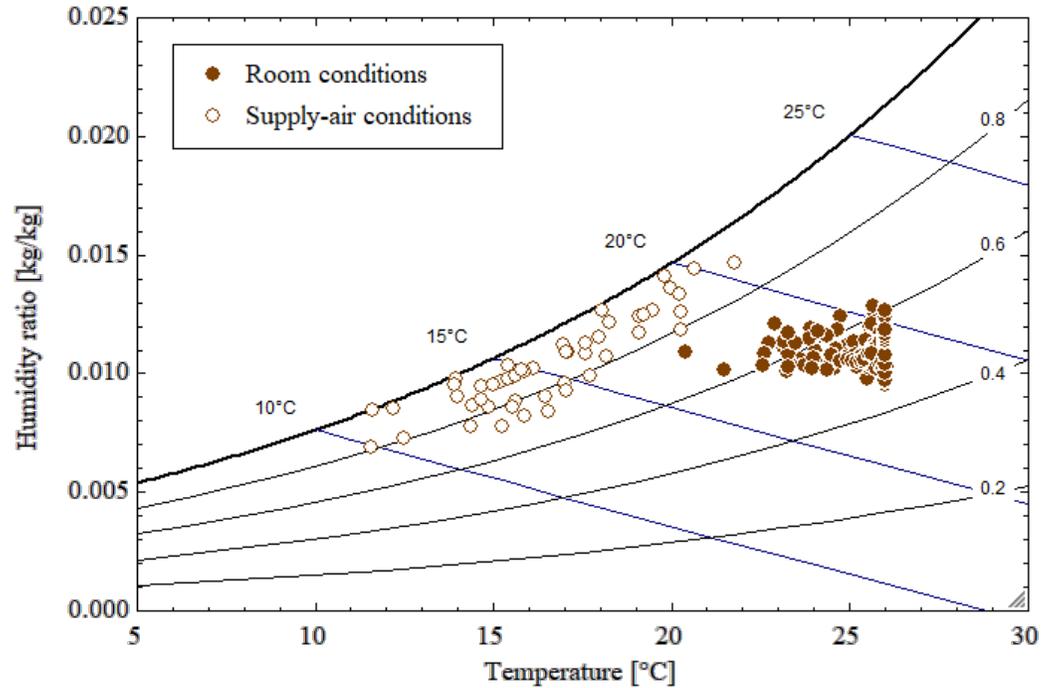

Low Energy Consumption Building

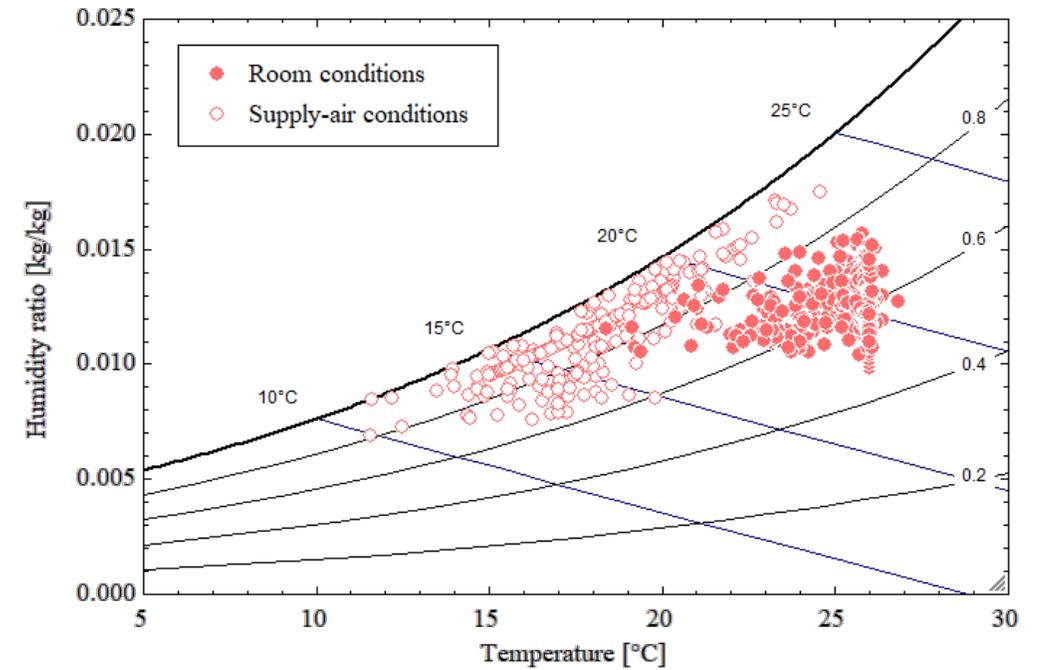

- As the energy performance of a building is enhanced, **sensible heat decreases rather than latent heat.**
- **Dehumidification** become more important in net ZEB.

Typical building

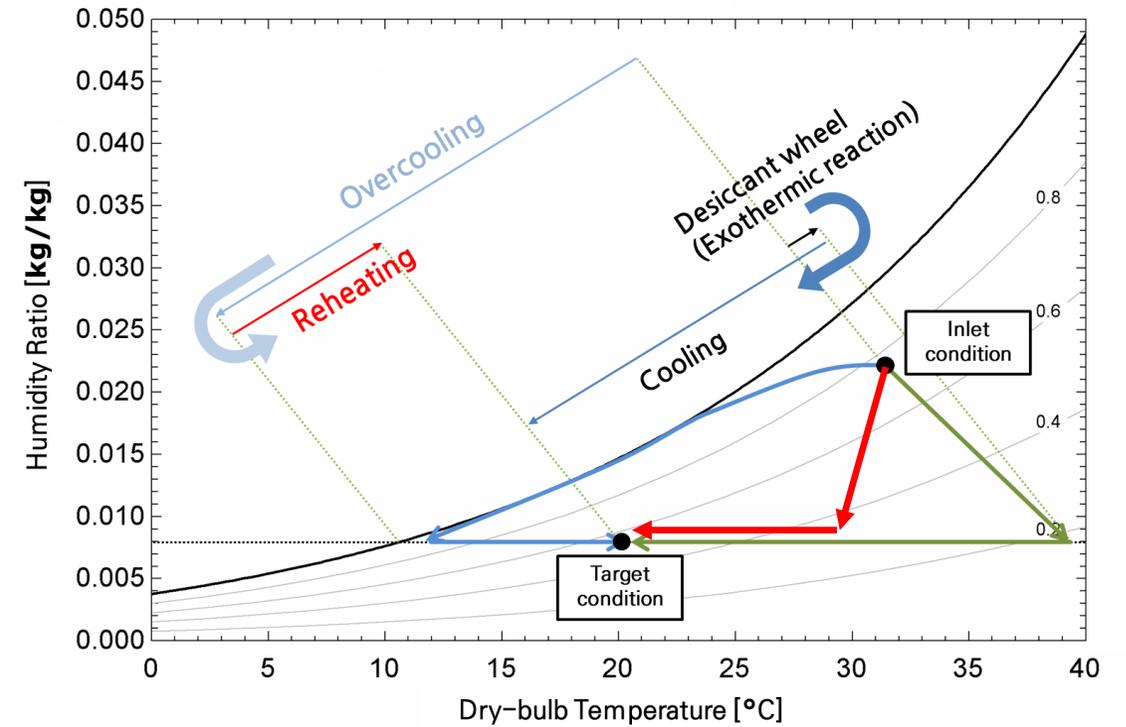

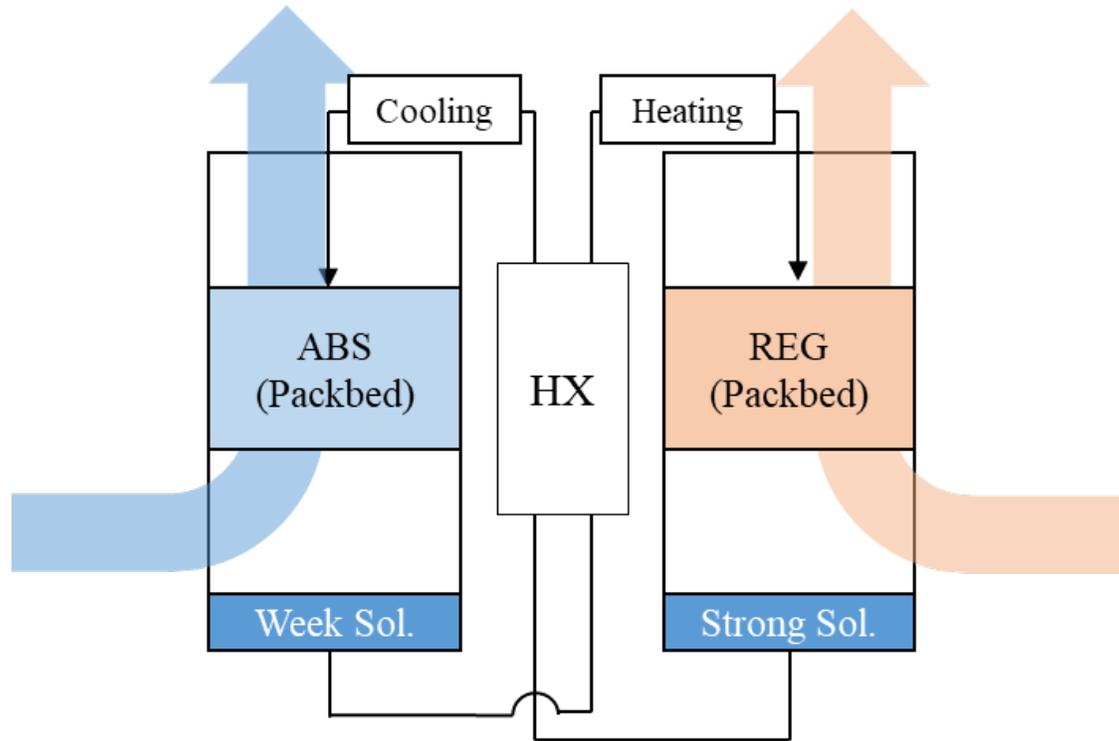

Frequency of satisfying the thermal comfort : over 95%

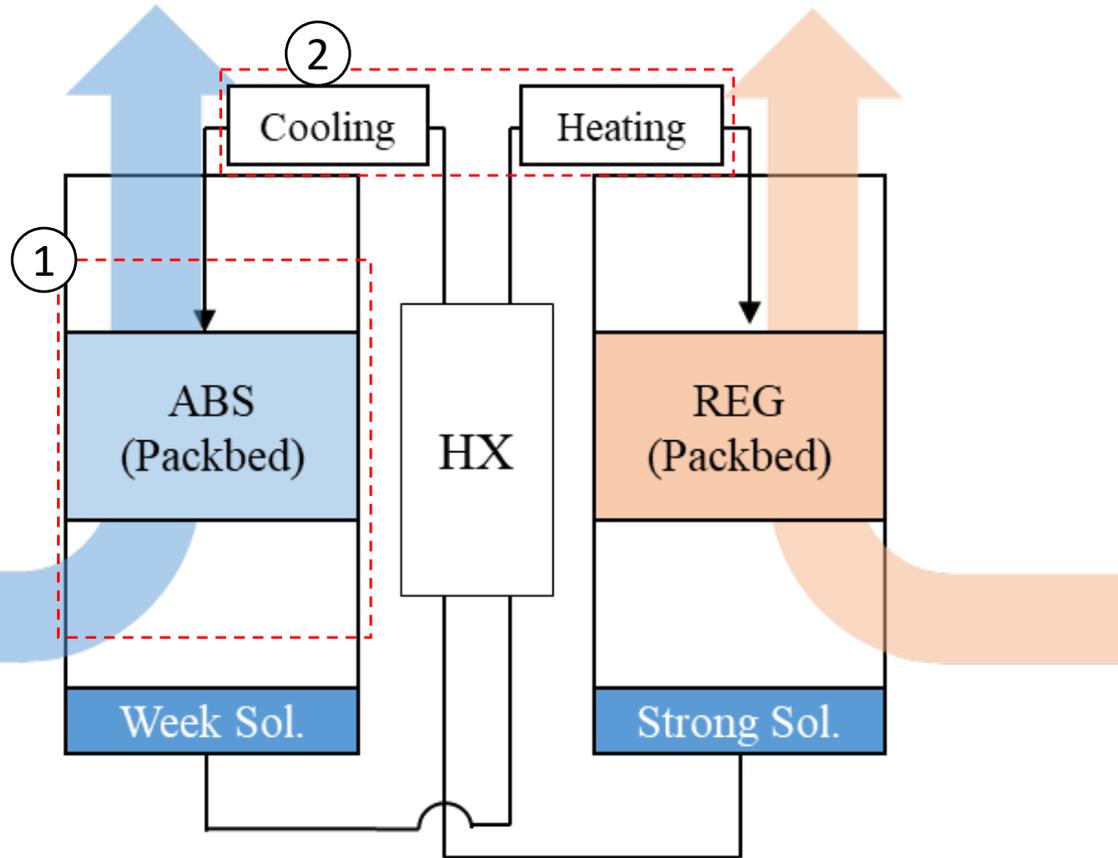

ZEB building

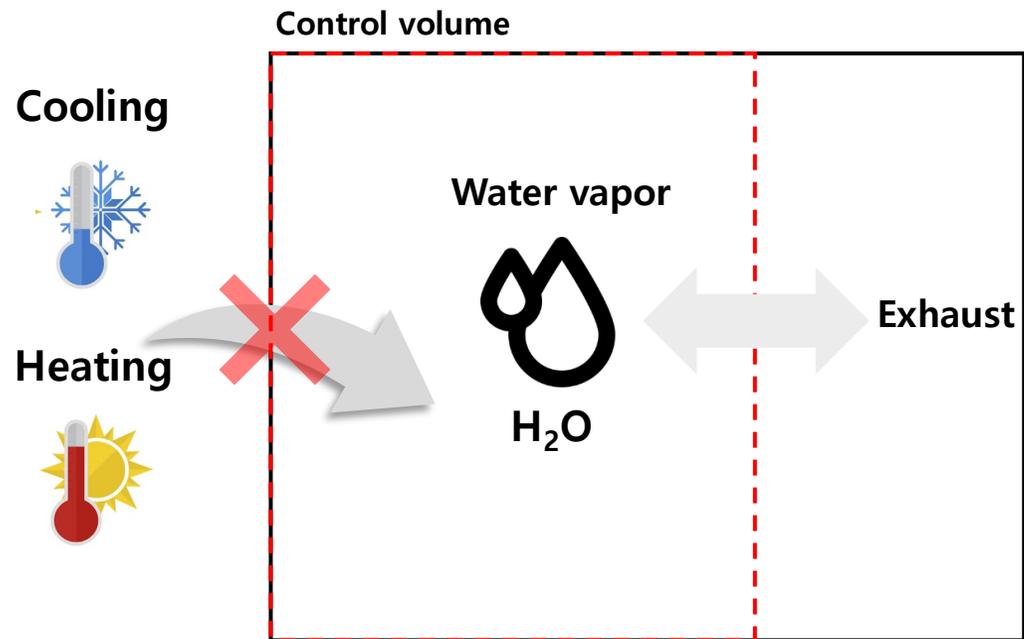

Frequency of satisfying the thermal comfort: less 50%

- Liquid desiccant system

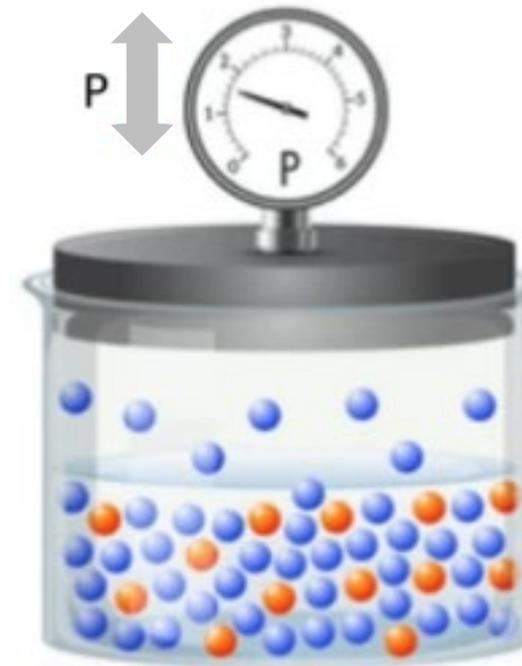

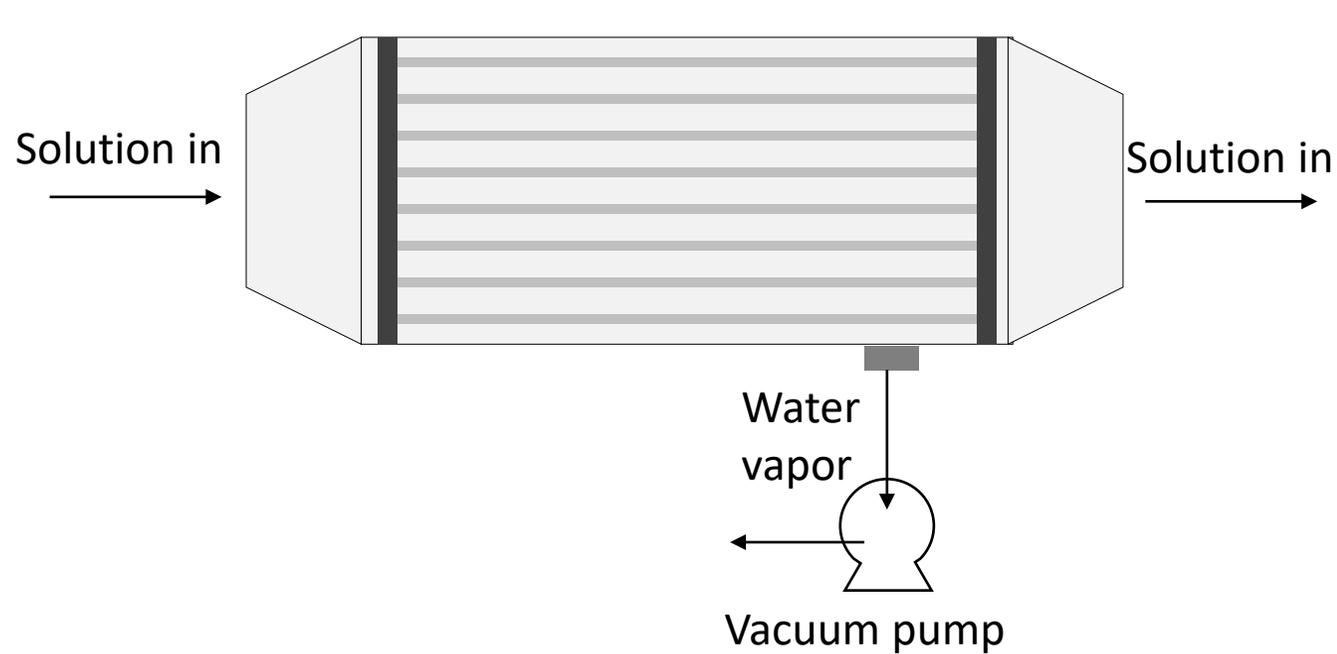

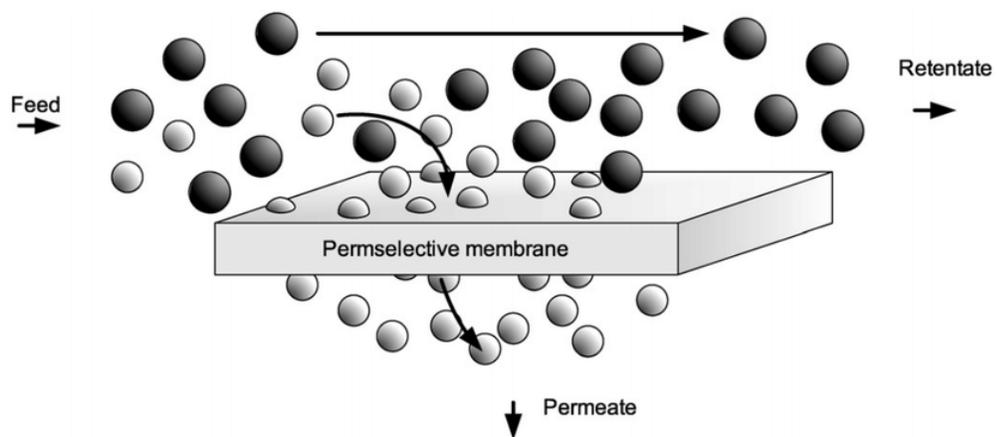

- 1) System configuration
- 2) Energy source

- Pressure control

- Membrane: Separation technology

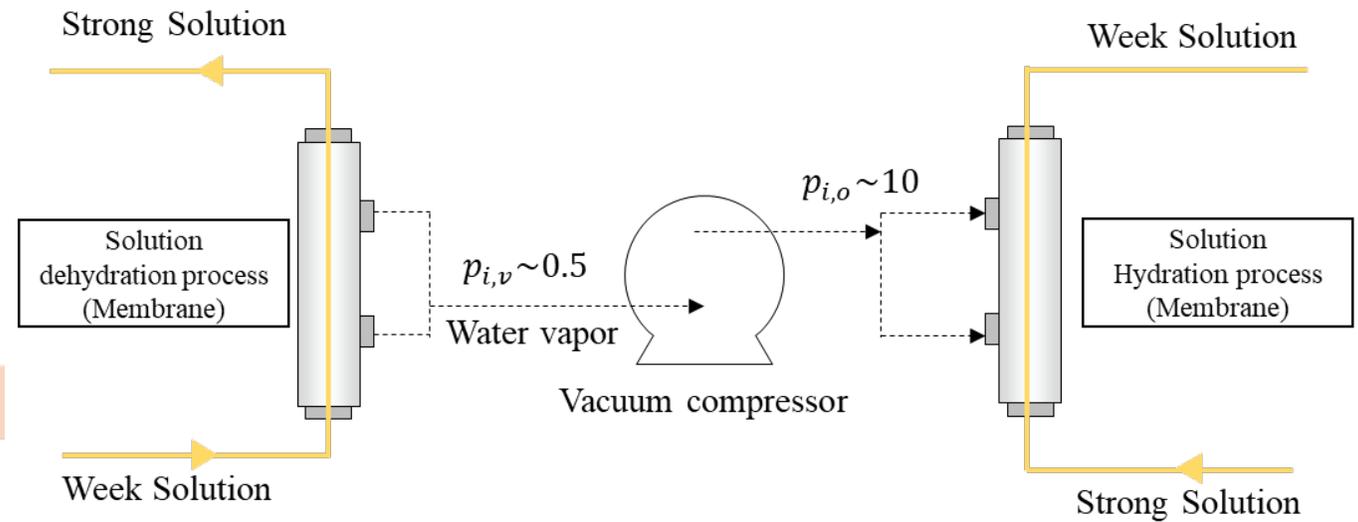

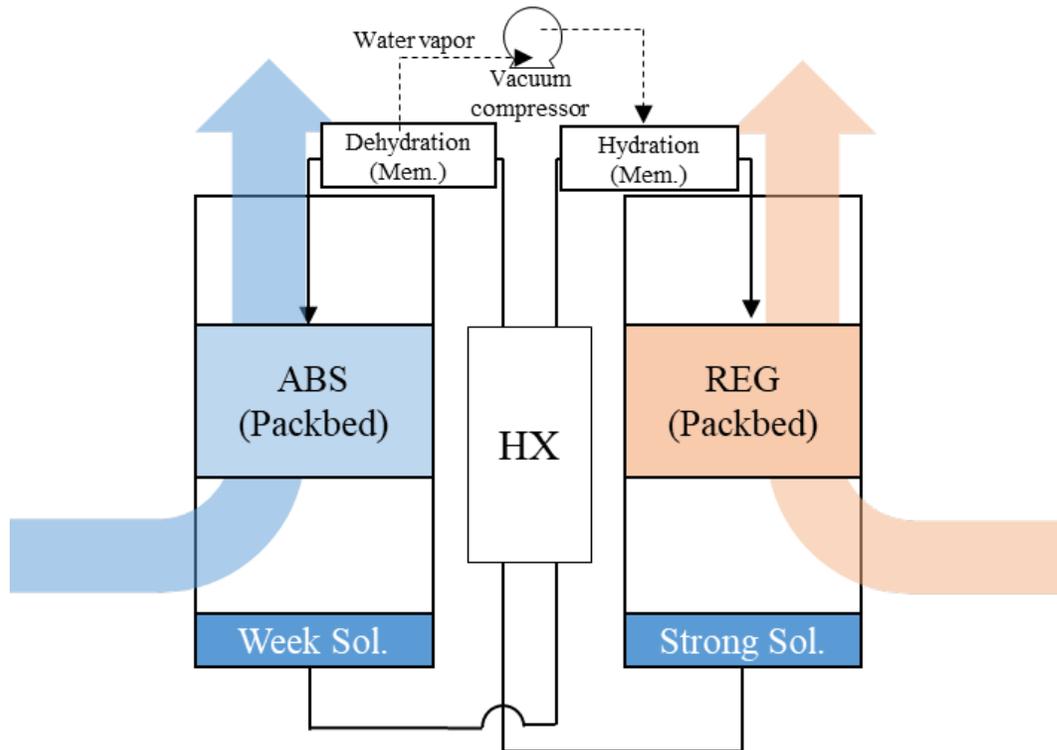

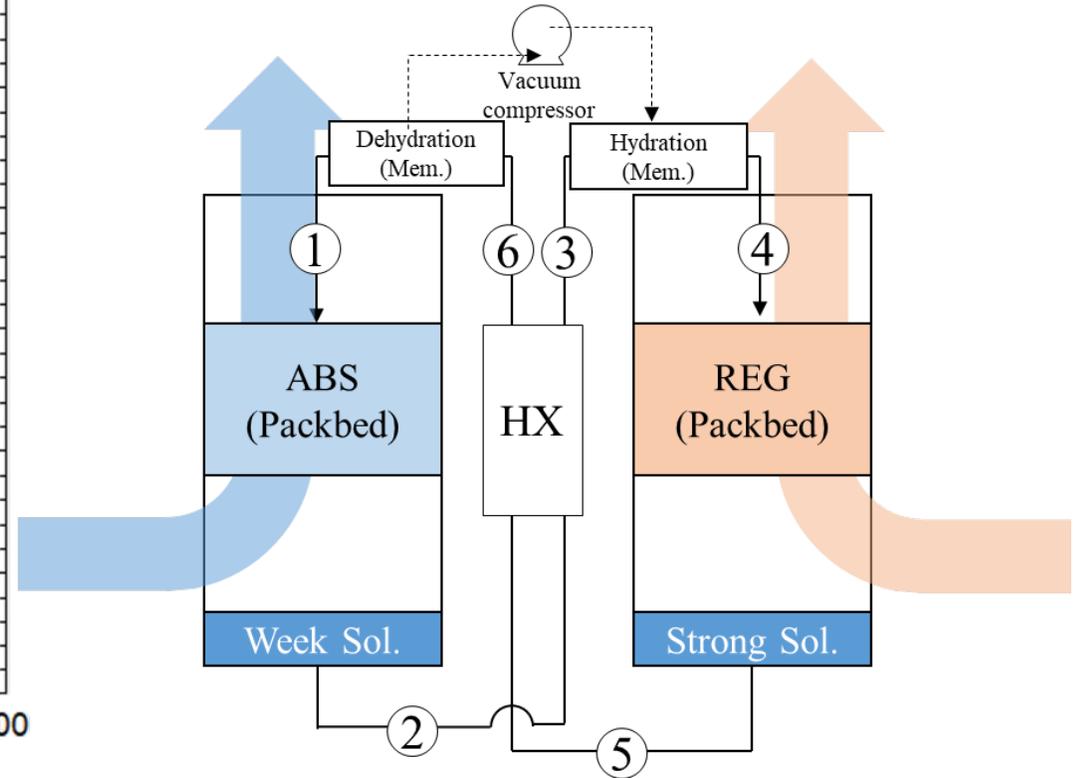

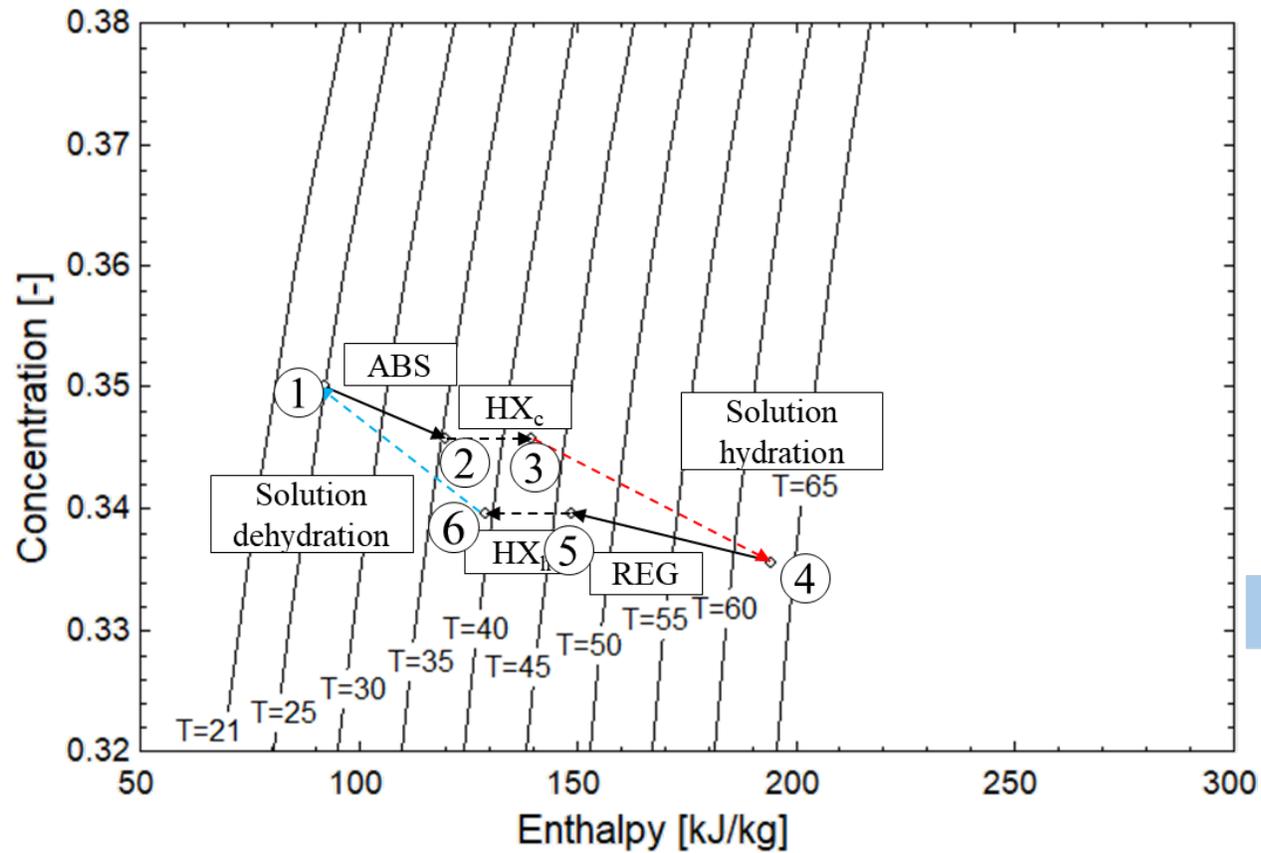

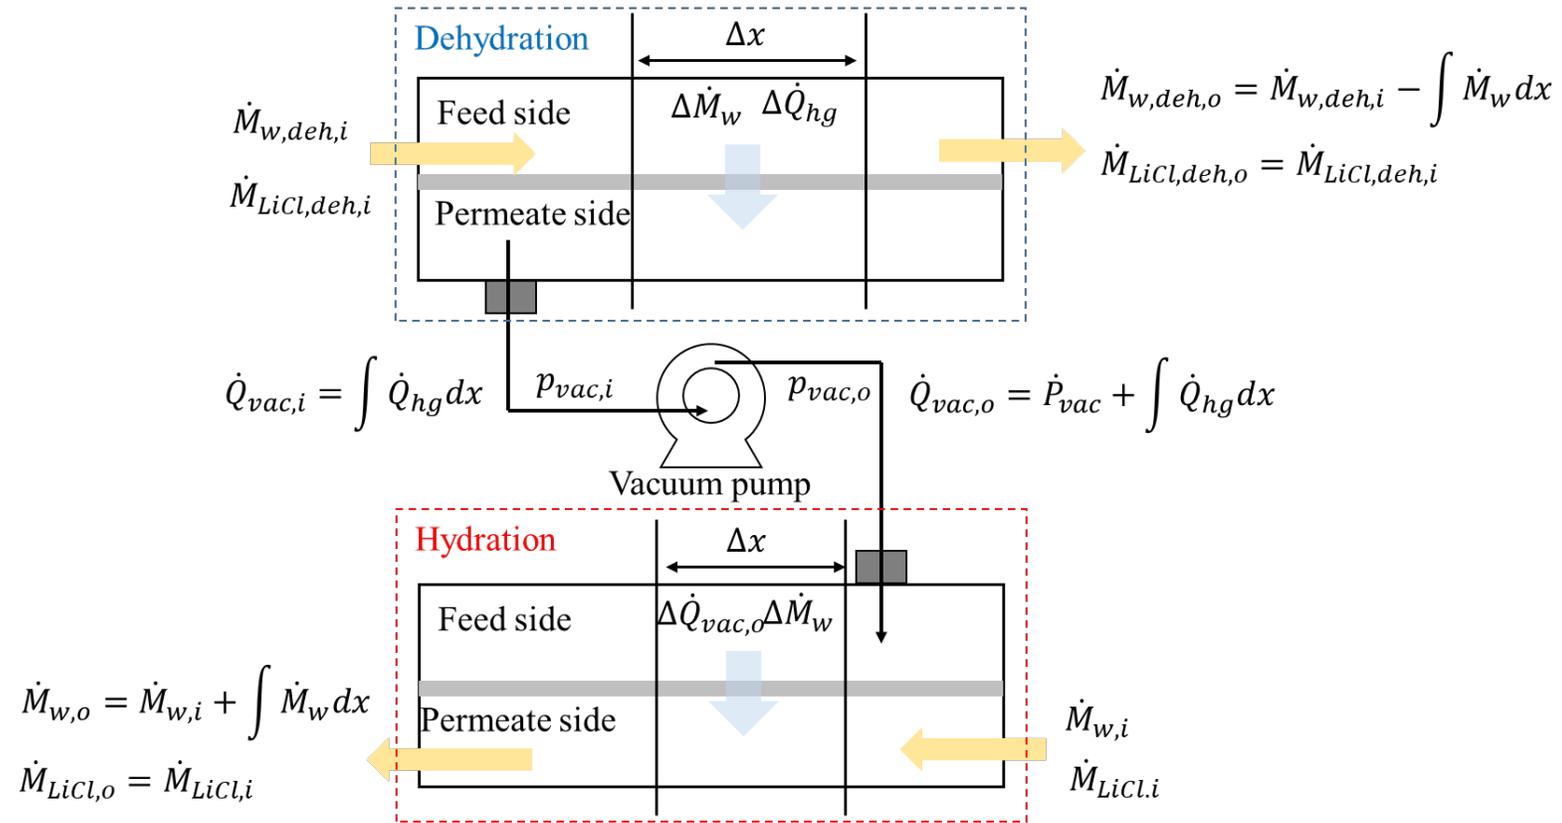

Introduction

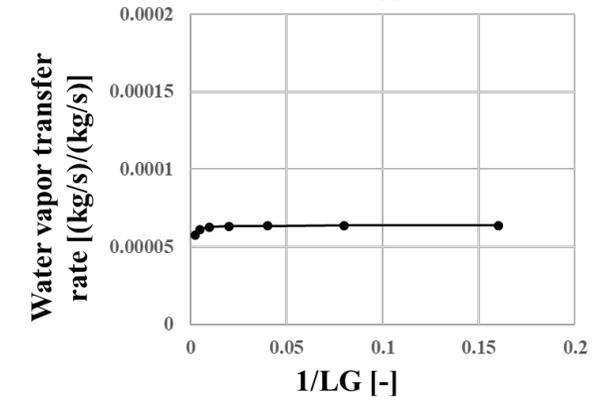

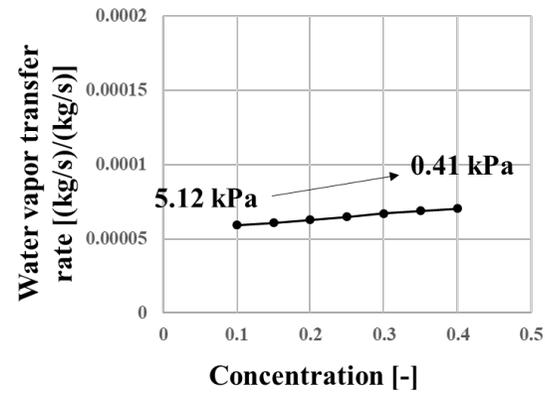

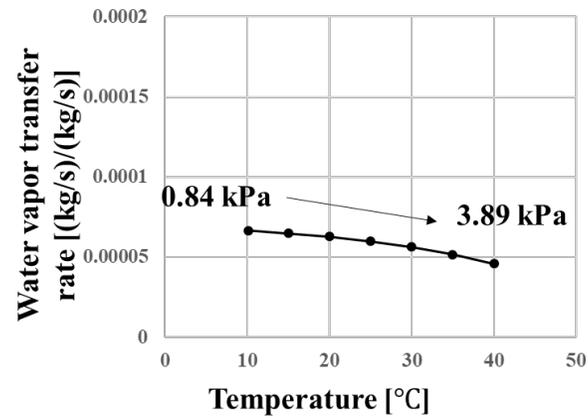

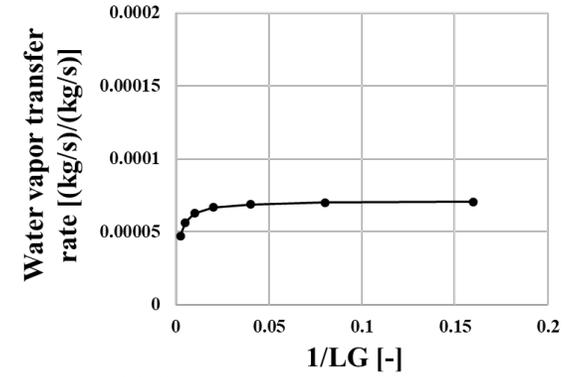

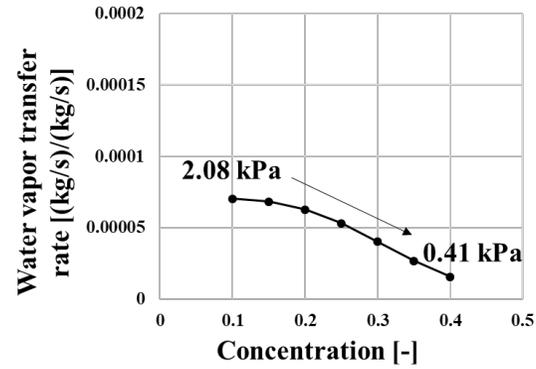

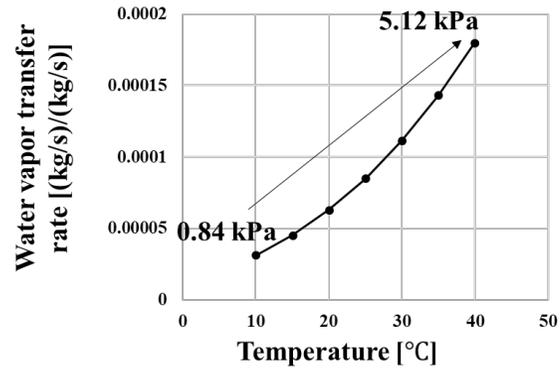

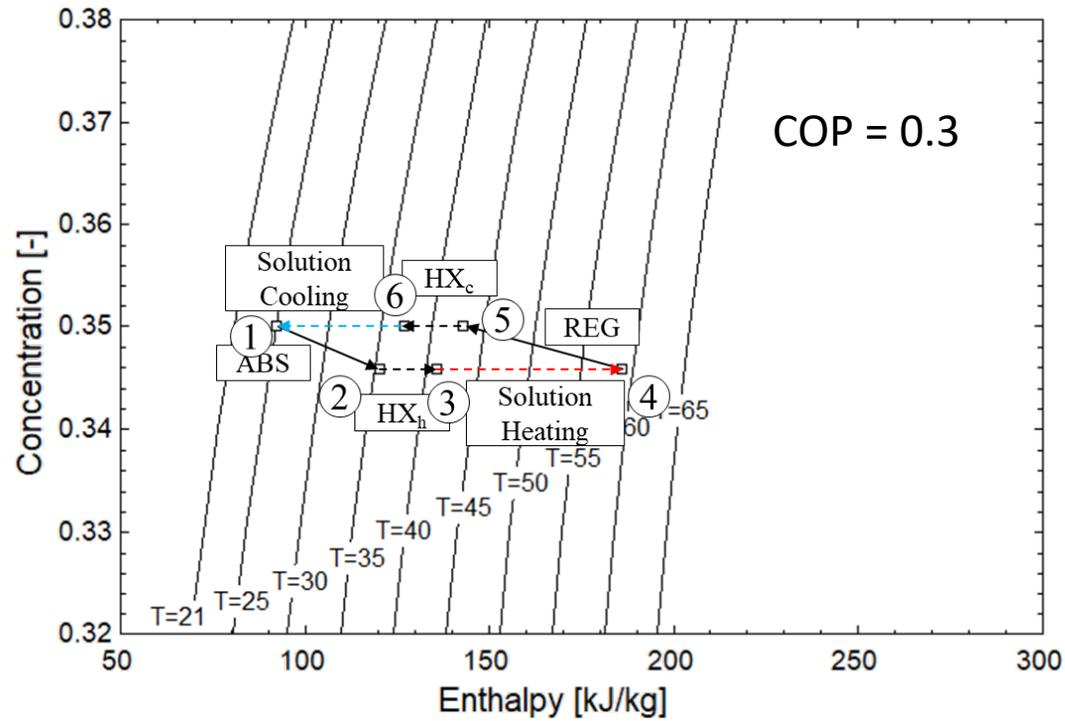

- Research Objective
 - 1) Proposal of a system that can dehumidify without using heat
 - 2) Analyzing the analysis method and impact of the system
 - 3) Heat and energy comparison with conventional systems

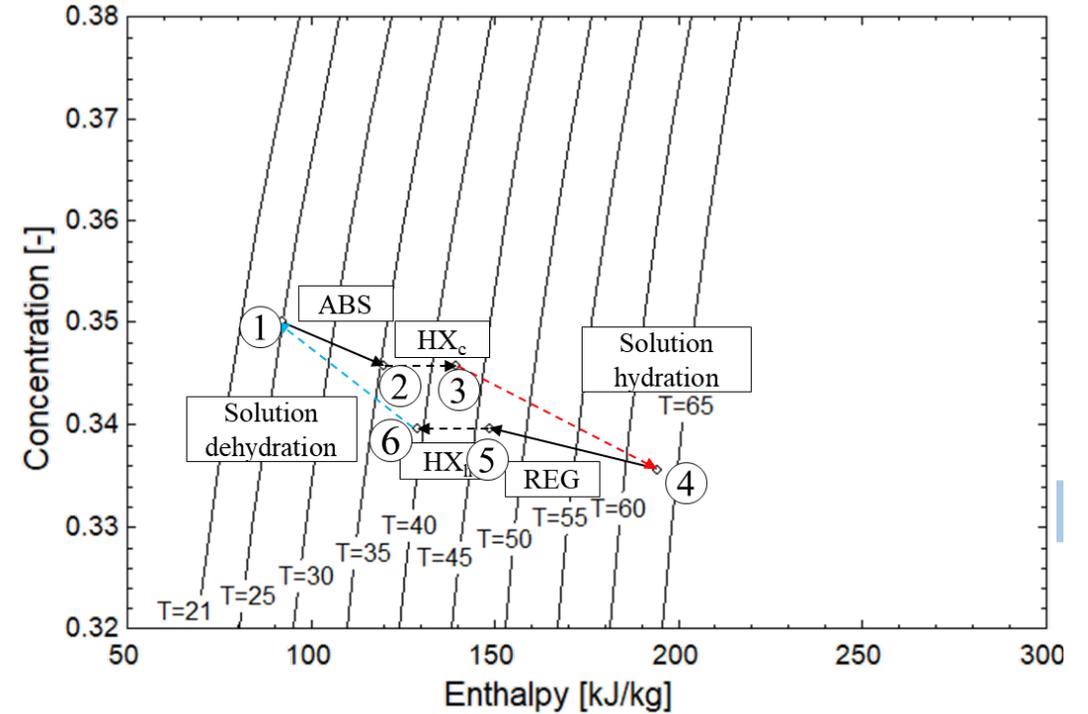

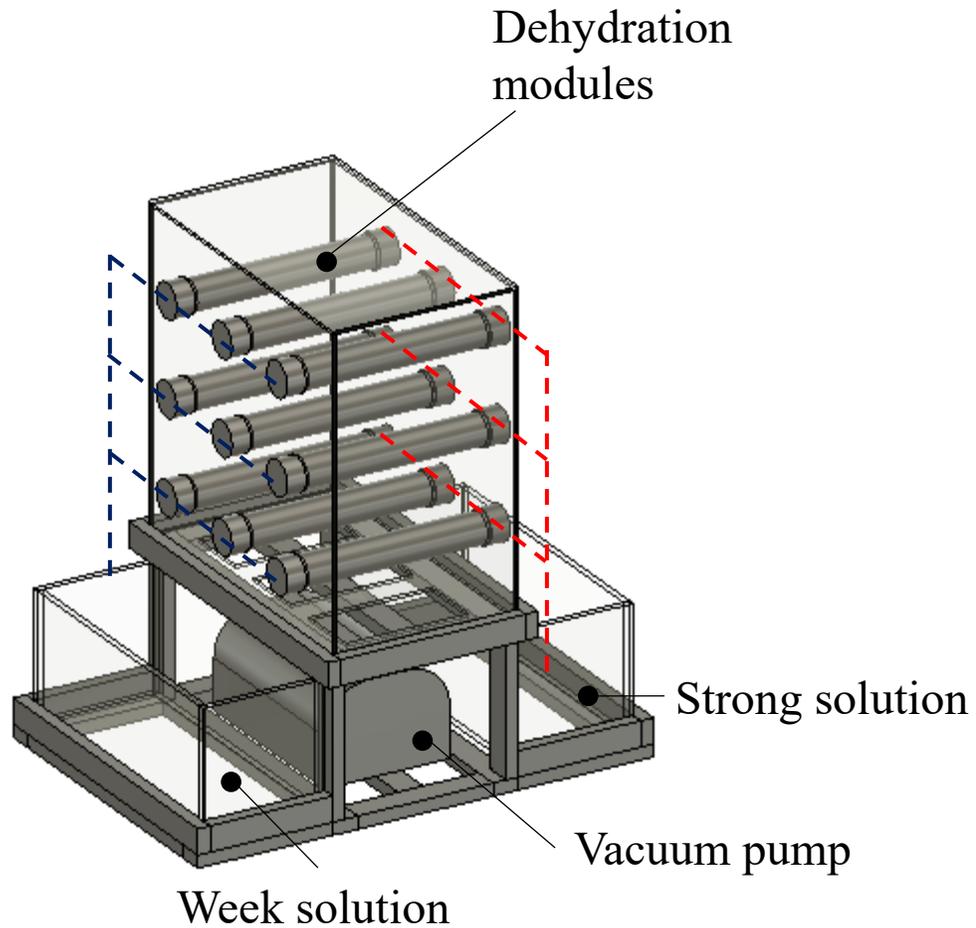

$$COP_{Ref} = \frac{Q_{a,c}}{Q_{h,s} + Q_{c,s}}$$

$$COP_{Pro} = \frac{Q_{a,c}}{P_{vac}} = \frac{Q_{a,c}}{Q_{Hyd} - Q_{dehyd}}$$

- 1) Experiment test for dehydration and hydration
- 2) Compare with numerical simulation

- Purpose

- We proposed a membrane-based liquid desiccant air conditioning system and its thermodynamic performance evaluated by equation-based simulation.

- Results

- The parametric study of the proposed system for dehumidification performance (mass transfer) showed that the solution temperature and concentration is mainly affected as driving force.
- Ideal COP (coefficient of performance) of the proposed system in the thermodynamic analysis is 1.55, which is 5.17 higher than that of the conventional liquid desiccant

- In further studies

- We will construct a prototype unit of proposed system, and experimentally analyze the effect of thermodynamic and energy performance of the proposed system.
